

MMA7455 3-Axis Accelerometer Module (#28526)

General Description

The Freescale Semiconductor MMA7455L 3-Axis Digital Output Accelerometer is a low power, micro-machined sensor capable of measuring acceleration along its X, Y, and Z axes. It offers several convenient integrated features including an analog to digital converter (ADC), digital low-pass filter, and selectable sensitivity ranges of $\pm 2g$, $\pm 4g$, or $\pm 8g$. This device can be easily configured to detect quick motion pulses as single-taps, double-taps, and 0g (free-fall) conditions on any or all axes and provides configurable interrupt pins (INT1 and INT2) for each type of event.

Flexibility and compatibility are designed into this module. An on-board voltage regulator and I/O voltage level-shifters make this module especially easy to connect to virtually any microcontroller. It operates over a wide range of supply voltages from 2.5 VDC to 5.5 VDC and communicates via Serial Peripheral Interface (SPI) or Inter-Integrated Circuit (I²C) bus.

Features

- Wide input voltage range
- Digital output (SPI/I²C)
- Selectable sensitivity: 8-bit mode ($\pm 2g/\pm 4g/\pm 8g$) or 10-bit mode ($\pm 8g$)
- User-configurable interrupts (INT1/INT2)
- User-settable registers for calibrating each axis
- Low current operation
- Compact, 8-pin DIP breadboard-friendly package: 0.5" x 0.6" (12.7 x 15.2 mm)

Application Ideas

- Inertial measurement units
- Tilt sensing for remote control systems
- Single-tap or double-tap user input
- Multi-axis vibration measurement
- Free-fall detection
- Motion sensing and data logging
- Model airplane flight stabilization

Key Specifications

- Power requirements: 2.5 – 5.5 VDC; 26 μA standby, 0.5 – 3 mA active
- Communication: SPI or I²C
- Dimensions: 0.5 x 0.6 x 0.46 in (12.7 x 15.2 x 11.7 mm)
- Operating temperature: -40 to +185 °F (-40 to +85 °C)

Note: Demonstration software files may be downloaded from the 28526 product page at www.parallax.com.

Package and Pin Descriptions

Pin #	Pin Name	Description	Pin Type
1	VIN	Input supply voltage	Power
2	n/c	Not connected – reserved for future use	n/a
3	INT1	Interrupt 1/Data Ready	Output
4	INT2	Interrupt 2	Output
5	GND	Ground	Power
6	CS	Chip select - SPI Enable (0), I ² C Enable (1)	Input
7	DATA	I ² C Serial Data (SDA), SPI Serial Data (SDI/SDO)	Input/Output
8	CLK	I ² C Serial Clock (SCL), SPI Serial Clock (SPC)	Input

Absolute Maximum Ratings

NOTE: These are conditions beyond which permanent device damage may occur; it is not implied that the device will function properly throughout this range. For operational ranges, see the Operating Conditions section below.

Parameter	Min	Typ	Max	Unit
V _{IN} (Measured from GND)	0	--	6.5	V
Storage temperature	-40	--	+125	°C
DATA Pin				
Input Voltage	-0.5	--	V _{IN} + 0.5	V
Pin Current	-50	--	+50	mA
Maximum Acceleration (all axes)	--	--	5000	g

Operating Conditions

Parameter	Min	Typ	Max	Unit
V _{IN} Supply Voltage	2.5	3.3 – 5	5.5	V
Supply Current ⁽¹⁾				
Operational (Sensing) Mode ⁽¹⁾⁽²⁾	--	437	555	µA
Operational Mode & Pins Loaded ⁽¹⁾⁽³⁾	--	<3	4.3	mA
Standby Mode ⁽¹⁾⁽⁴⁾	--	26	42	µA
Operating Temperature Range	-40	25	85	°C
Output Data (Measurement) Rate				
Data Rate is 125 Hz when 62.5 Hz BW selected	--	125	--	Hz
Data Rate is 250 Hz when 125 Hz BW selected	--	250	--	Hz
Sensitivity ⁽⁵⁾ ±2g range, 8-bit	58	64	70	count/g
0g Output Signal ⁽⁵⁾ ±2g range, 8-bit	-21	0	21	count
SPI Clock Frequency	--	4	--	MHz

Notes:

1. Supply current measured flowing into VIN pin. V_{IN} = 5.5 V
2. Operational Mode current measured with MMA7455L device placed in Measurement Mode and CLK, DATA, and CS pins disconnected.
3. Operation Mode & Pins Loaded is measured as worst-case current draw with CLK, DATA, and CS pins all connected to ground; INT1 and INT2 pins left disconnected.
4. Standby Mode current measured with MMA7455L device placed in standby mode and CLK and DATA lines left high (connected to V_{IN}) or disconnected. Value may be higher if these lines are loaded.
5. Values taken from Freescale Semiconductor MMA7455L device specifications.

Principle of Operation

The Freescale MMA7455L is a surface-machined Micro Electro-mechanical System (MEMS) formed by masking and etching semiconductor materials. It can be visualized as a very small mass suspended in the center of the device by tiny springs. When an acceleration is applied to the device, the mass deflects along one or more axes inside the device. Built-in circuitry constantly measures the amount of deflection along each axis and translates it into acceleration data. Then the data becomes available to be read by an external microcontroller. For more detailed information refer to the Freescale MMA7455L product documentation.

I/O Level Shifting

Part of what makes this 3-Axis Accelerometer module so useful is its wide power supply and I/O voltage compatibility range of 2.5 V to 5.5 V. The MMA7455L device operates over a supply voltage range of 2.4 V to 3.6 V; so to make it compatible with devices operating up to 5.5 V, a 3.3 V Low Dropout (LDO) voltage regulator was installed, as well as two types of level shifting circuits. This allows the device to operate and communicate over the full voltage supply range.

For the DATA pin, a bi-directional level shifting IC is used to translate the lower I/O voltage of the MMA7455L to the possibly higher voltage used by an externally connected device. This particular level shifter has built-in pull-up resistors to each supply rail so it can be driven by open drain outputs for I²C; but can also be driven low/high for SPI protocol. Additionally, it automatically detects the direction of data flow and switches the output drivers accordingly.

The CLK and CS pins operate exclusively as inputs, so simpler and cheaper level shifting circuits can be used. Only a resistor and Schottky diode are required for each pin. See the Module Schematic section for details. When an external device drives the CLK or CS pin low, the I/O pin on the MMA7455L is pulled

down through the Schottky diode to about 0.35 V. This is plenty low enough to be read as a logic low (0) by the MMA7455L accelerometer device. When the CLK or CS pin is driven high or left floating, it gets pulled up to the local V_{CC} by the 2.2k Ω resistor. Meanwhile, the diode prevents the possibility of higher external voltages damaging the input pin on the MMA7455L.

Measured Acceleration Output Values

The MMA7455L converts a detected acceleration into a number which can easily be read by an external microcontroller. The number it generates depends on the sensitivity of the device which can be $\pm 2g$, $\pm 4g$, or $\pm 8g$. One g represents the acceleration due to the earth's gravity: $1g \approx 9.8m/s^2$ or $1g \approx 32.2ft/s^2$. Of course this value varies depending on the object's latitude and distance from sea level. From a sensory standpoint, there is no detectable difference between forces observed under the influence of acceleration and forces observed under the influence of gravity. Using units of g's is simply a convenient way of relating the magnitude of a measured acceleration to the familiar force of gravity.

The full measurement range is divided up into a number of counts which is determined by the number of bits specified for the data; 8-bit data has 256 counts, and 10-bit data has 1,024 counts. The value of one count, or least significant bit (LSB) of data, can be determined as follows:

$$\text{One LSB} = \frac{\text{Full g-range}}{\text{Number of counts}}$$

So for a sensitivity range of $\pm 2g$ (full range = 4g) in 8-bit mode (256 counts), the value of one LSB would be approximately:

$$\text{One LSB} = \frac{4g}{256 \text{ counts}} \approx 0.016 \frac{g}{\text{count}}$$

A few key numerical output values over each acceleration range for 8-bit data are shown below for reference.

Sensitivity range	Acceleration	Output Value (hex/decimal)	
$\pm 2g$	-2g	\$81	-127
	-1g	\$C1	-63
	0g	\$00	0
	+1g	\$3F	63
	+2g	\$7F	127
$\pm 4g$	-4g	\$81	-127
	-1g	\$E1	-31
	0g	\$00	0
	+1g	\$1F	31
	+4g	\$7F	127
$\pm 8g$	-8g	\$81	-127
	-1g	\$F1	-15
	0g	\$00	0
	+1g	\$0F	15
	+8g	\$7F	127

Module Schematic

Quick Start Guide

The following is a very basic procedure to get started initializing and reading values from the Digital 3-Axis Accelerometer module. All the features of the MMA7455L accelerometer are covered in full detail in the Freescale Semiconductor MMA7455L device datasheet. Example test code as well as more advanced code demonstrations of this device for the Propeller and Basic Stamp can be found on the 28526 product page at www.parallax.com.

1. With main power off, make the proper connections between the accelerometer and a microcontroller as shown below according to whether SPI or I²C is used. The voltage connected to the VIN pin should be the same as the voltage powering the microcontroller communicating with the device. The value of the pull-up resistors used in I²C mode depend on the desired data rate, and the total capacitance of the bus. A reasonable starting value for each pull-up resistor is 4.7kΩ. This value may need to be reduced if many devices are connected on the bus (which increases the bus capacitance), or if high data rates are required.

2. Power on the device and initialize the "Mode Control" register (\$16 MCTL). For example: writing a value of \$25 (%00100101) configures the device for SPI 3-wire mode, $\pm 2g$ measurement range, and puts the device in measurement mode rather than its default standby mode. Refer to the MMA7455L device datasheet for information on proper SPI or I²C communication protocol to send and receive data.
3. The device is ready to be read by the microcontroller. Be sure to read from the correct data registers depending on whether 8-bit ($\pm 2g$, $\pm 4g$, $\pm 8g$) or 10-bit ($\pm 8g$) data is used. For example: reading the XOUT8 (\$06) data register returns the 8-bit value for acceleration along the x-axis. Continue reading data from any other desired axes (YOUT8, or ZOUT8). This operation can be performed in a continuous loop in software, or intermittently when required by the application.

±2g/±4g/±8g Three Axis Low-g Digital Output Accelerometer

The MMA7455L is a Digital Output (I²C/SPI), low power, low profile capacitive micromachined accelerometer featuring signal conditioning, a low pass filter, temperature compensation, self-test, configurable to detect 0g through interrupt pins (INT1 or INT2), and pulse detect for quick motion detection. 0g offset and sensitivity are factory set and require no external devices. The 0g offset can be customer calibrated using assigned 0g registers and g-Select which allows for command selection for 3 acceleration ranges (2g/4g/8g). The MMA7455L includes a Standby Mode that makes it ideal for handheld battery powered electronics.

Features

- Digital Output (I²C/SPI)
- 3mm x 5mm x 1mm LGA-14 Package
- Low Current Consumption
- Self-Test for Z-Axis
- Low Voltage Operation: 2.4 V – 3.6 V
- User Assigned Registers for Offset Calibration
- Programmable Threshold Interrupt Output
- Level Detection for Motion Recognition (Shock, Vibration, Freefall)
- Pulse Detection for Single or Double Pulse Recognition
- Sensitivity (64 LSB/g @ 2g and @ 8g in 10-Bit Mode)
- Selectable Sensitivity (±2g, ±4g, ±8g) for 8-bit Mode
- Robust Design, High Shocks Survivability (5,000g)
- RoHS Compliant
- Environmentally Preferred Product
- Low Cost

Typical Applications

- Cell Phone/PMP/PDA: Image Stability, Text Scroll, Motion Dialing, Tap to Mute
- HDD: Freefall Detection
- Laptop PC: Freefall Detection, Anti-Theft
- Pedometer
- Motion Sensing, Event Recorder

Storage Temperature Range	T_{stg}	-40 to +125	°C

ELECTRO STATIC DISCHARGE (ESD)

WARNING: This device is sensitive to electrostatic discharge.

Although the Freescale accelerometer contains internal 2000V ESD protection circuitry, extra precaution must be taken by the user to protect the chip from ESD. A charge of over 2000 volts can accumulate on the human body or associated test equipment. A charge of this magnitude can alter the performance or cause failure of the chip. When handling the accelerometer, proper ESD precautions should be followed to avoid exposing the device to discharges which may be detrimental to its performance.

Table 3. Operating Characteristics

Unless otherwise noted: $-40^{\circ}\text{C} \leq T_A \leq 85^{\circ}\text{C}$, $2.4\text{ V} \leq AV_{DD} \leq 3.6\text{ V}$, Acceleration = 0g, Loaded output.

Time Window (Adjustable range)		1	—	250	ms
Bandwidth for detecting interrupt*		—	600	—	Hz
Time step for latency timer and time window		—	1	—	ms

Note: The response time is between 10% of full scale V_{DD} input voltage and 90% of the final operating output voltage.

*The bandwidth for detecting interrupts in level and pulse is 600Hz which is changed from measurement mode.

PRINCIPLE OF OPERATION

The Freescale accelerometer is a surface-micromachined integrated-circuit accelerometer. The device consists of a surface micromachined capacitive sensing cell (g-cell) and a signal conditioning ASIC contained in a single package. The sensing element is sealed hermetically at the wafer level using a bulk micromachined cap wafer. The g-cell is a mechanical structure formed from semiconductor materials (polysilicon) using semiconductor processes (masking and etching). It can be modeled as a set of beams attached to a movable central mass that move between fixed beams. The movable beams can be deflected from their rest position by subjecting the system to an acceleration (Figure 2).

As the beams attached to the central mass move, the distance from them to the fixed beams on one side will increase by the same amount that the distance to the fixed beams on the other side decreases. The change in distance is a measure of acceleration. The g-cell beams form two back-to-back capacitors (Figure 2). As the center beam moves with acceleration, the distance between the beams changes and each capacitor's value will change, ($C = A\epsilon/D$). Where A is the area of the beam, ϵ is the dielectric constant, and D is the distance between the beams.

The ASIC uses switched capacitor techniques to measure the g-cell capacitors and extract the acceleration data from the difference between the two capacitors. The ASIC also signal conditions and filters (switched capacitor) the signal, providing a digital output that is proportional to acceleration.

Figure 2. Simplified Transducer Physical Model

FEATURES

Self-Test

The sensor provides a self-test feature that allows the verification of the mechanical and electrical integrity of the accelerometer at any time before or after installation. This feature is critical in applications such as hard disk drive protection where system integrity must be ensured over the life of the product. When the self-test function is initiated through the mode control register (\$16), accessing the “self-test” bit, an electrostatic force is applied to each axis to cause it to deflect. The Z-axis is trimmed to deflect 1g. This procedure assures that both the mechanical (g-cell) and electronic sections of the accelerometer are functioning.

g-Select

The g-Select feature enables the selection between 3 acceleration ranges for measurement. Depending on the values in the Mode control register (\$16), the MMA7455L's internal gain will be changed allowing it to function with a 2g, 4g or 8g measurement sensitivity. This feature is ideal when a product has applications requiring two or more acceleration ranges for optimum performance and for enabling multiple functions. The sensitivity can be changed during the operation by modifying the two GLVL bits located in the mode control register.

\$16: Mode Control Register (Read/Write)

D7	D6	D5	D4	D3	D2	D1	D0	Bit

GLVL [1:0]	g-Range	Sensitivity
00	8g	16 LSB/g
01	2g	64 LSB/g
10	4g	32 LSB/g

Standby Mode

This digital output 3-axis accelerometer provides a standby mode that is ideal for battery operated products. When standby mode is active, the device outputs are turned off, providing significant reduction of operating current. When the device is in standby mode the current will be reduced to 2.5 μ A typical. In standby mode the device can read and write to the registers with the I²C/SPI available, but no new measurements can be taken in this mode as all current consuming parts are off. The mode of the device is controlled through the mode control register by accessing the two mode bits as shown in [Table 6](#).

Table 6. Configuring the Mode using Register \$16 with MODE[1:0] bits.

MODE [1:0]	Function
00	Standby Mode
01	Measurement Mode
10	Level Detection Mode
11	Pulse Detection Mode

Measurement Mode

During measurement mode, continuous measurements on all three axes enabled. The g-range for 2g, 4g, or 8g are selectable with 8-bit data and the g-range of 8g is selectable with 10-bit data. The sample rate during measurement mode is 125 Hz with 62.5 BW filter selected. The sample rate is 250 Hz with the 125 Hz filter selected. Therefore, when a conversion is complete (signaled by the DRDY flag), the next measurement will be ready.

When measurements on all three axes are completed, a logic high level is output to the DRDY pin, indicating "measurement data is ready." The DRDY status can be monitored by the DRDY bit in Status Register (Address: \$09). The DRDY pin is kept high until one of the three Output Value Registers are read. If the next measurement data is written before the previous data is read, the DOVR bit in the Status Register will be set. Also note that in measurement mode, level detection mode and pulse detection mode are not available.

By default all three axes are enabled. X and/or Y and/or Z can be disabled. There is a choice between detecting an absolute signal or a positive or negative only signal on the enabled axes. There is also a choice between doing a detection for motion where X or Y or Z > Threshold vs. doing a detection for freefall where X & Y & Z < Threshold.

LEVEL DETECTION

When in Level or Pulse detection mode, it is not advisable to read the XYZ measurements because this can conflict with timing. The interrupts for level and pulse detection are at 600 Hz, while measurement mode is at 125 Hz. It is best to exit the pulse/level mode before taking a measurement on the XYZ.

Both the Level Detection and Pulse Detection modes can trigger an interrupt. Typically one interrupt is assigned to either pulse detection or level detection. To detect both at the same time 2 interrupts are required. The level detection mechanism has no timers associated with it. Once a set acceleration level is reached the interrupt pin will go high and remain high until the interrupt pin is cleared (See [Assigning, Clearing & Detecting Interrupts](#)).

By default all three axes are enabled and the detection range is 8g only. X and/or Y and/or Z can be disabled. There is a choice between detecting an Absolute signal or a Positive or Negative only signal on the enabled axes. There is also a choice between doing a detection for Motion where X or Y or Z > Threshold vs. doing a detection for Freefall where X & Y & Z < Threshold.

THRESHOLD DETECTION FOR MOTION AND FREEFALL CONDITIONS

CASE 1: Motion Detection

Integer Value: $X > \text{Threshold}$ **OR** $Y > \text{Threshold}$ **OR** $Z > \text{Threshold}$

Reg \$18 THOPT=1; Reg 19 LDPL=0, Set Threshold to 3g, which is 47 counts (16 counts/g). Set register \$1A LDTH = \$2F.

CASE 2: Motion Detection

Absolute: $||X|| > \text{Threshold}$ **OR** $||Y|| > \text{Threshold}$ **OR** $||Z|| > \text{Threshold}$

Reg \$18 THOPT=0; Reg 19 LDPL=0, Set Threshold to 3g, which is 47 counts (16 counts/g). Set register \$1A LDTH = \$2F.

CASE 3: Freefall Detection

Integer Value: $X < \text{Threshold}$ **AND** $Y < \text{Threshold}$ **AND** $Z < \text{Threshold}$

Reg \$18 THOPT=1; Reg 19 LDPL=1, Set Threshold to 0.5g, which is 7 counts (16 counts/g). Set register \$1A LDTH = \$07

CASE 4: Freefall Detection

Absolute: $||X|| < \text{Threshold}$ **AND** $||Y|| < \text{Threshold}$ **AND** $||Z|| < \text{Threshold}$

Reg \$18 THOPT=0; Reg 19 LDPL=1, Set Threshold to +/-0.5g, which is 7 counts (16 counts/g). Set register \$1A LDTH = \$07.

PULSE DETECTION

There are two interrupt pins available for detection of level and pulse conditions. The pulse detection has several timing windows associated with it. A single pulse and a double pulse can be detected. Also freefall can be detected. The interrupt pins can be assigned to detect the first pulse on one interrupt and the second pulse on the other interrupt. This is explained on [Page page 15](#), under the [Assigning, Clearing & Detecting Interrupts](#) section.

By default all three axes are enabled and the detection range is 8g only. X and/or Y and/or Z can be disabled. There is a choice between doing a detection for Motion detection vs. doing a detection for Freefall.

\$18: Control 1 (Read/Write): Disable X, Y or Z for pulse detection

This allows the user to define how many axes to use for detection. All axes are enabled by default. To disable write 1

XDA: Disable X

YDA: Disable Y

ZDA: Disable Z.

When any of the events are detected, the interrupt pin (either INT1 or INT2) will go high. The interrupt pin assignment is set up in **Register \$18**, discussed in the [Assigning, Clearing & Detecting Interrupts](#) section on [page 15](#). The detection status is monitored by the detection source register \$0A.

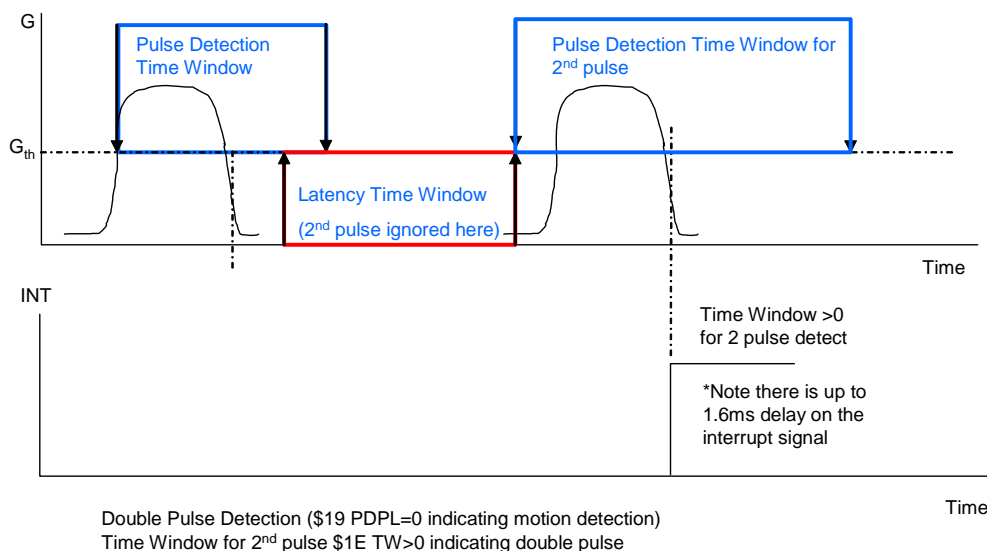

Figure 5. Double Pulse Detection

ASSIGNING, CLEARING & DETECTING INTERRUPTS

Assigning the interrupt pins is done in Register \$18. There are 3 combinations for the interrupt pins to be assigned which are outlined below in the table for INTREG[1:0].

\$18 Control 1 Register

D7	D6	D5	D4	D3	D2	D1	D0	Reg \$18
DFBW	THOPT	ZDA	YDA	XDA	INTREG[1]	INTREG[0]	INTPIN	Function
0	0	0	0	0	0	0	0	Default

Table 7. Configuring the Interrupt settings using Register \$18 with INTREG[1:0] bits

INTREG[1:0]	"INT1" Register Bit	"INT2" Register Bit
00	Level detection	Pulse Detection
01	Pulse Detection	Level Detection
10	Single Pulse detection	Single or Double Pulse Detection

00:

01: INT1 Register is detecting Pulse while INT2 is detecting Level.

10: INT1 Register is detecting a Single Pulse and INT2 is detecting Single Pulse (if 2nd Time Window = 0) or if there is a latency time window and second time window > 0 then INT2 will detect the double pulse only.

INTPIN: INT1 pin is routed to INT1 bit in Detection Source Register (\$0A) and INT2 pin is routed to INT2 bit in Detection Source Register (\$0A).

INTPIN: INT2 pin is routed to INT1 bit in Detection Source Register (\$0A) and INT1 pin is routed to INT2 bit in Detection Source Register (\$0A).

Note: When INTREG[1:0] = 10 for the condition to detect single pulse on INT1 and either single or double pulse on INT2, INT1 register bit can no longer be cleared by setting CLR_INT1 bit. It is cleared by setting CLR_INT2 bit. In this case, setting CLR_INT2 clears both INT1 and INT2 register bits and resets the detection operation. Follow the example given for clearing the interrupts.

Clearing the Interrupt Pins: Register \$17

\$17: Interrupt Latch Reset (Read/Write)

D7	D6	D5	D4	D3	D2	D1	D0	Reg \$17
--	--	--	--	--	--	CLR_INT2	CLR_INT1	Function
0	0	0	0	0	0	0	0	Default

CLR_INT1

1: Clear "INT1"

0: Do not clear "INT1"

CLR_INT2

1: Clear "INT2"

0: Do not clear "INT2"

After interrupt has triggered due to a detection, the interrupt pin (INT1 or INT2) need to be cleared by writing a logic 1. Then the interrupt pin should be enabled to trigger the next detection by setting it to a logic 0.

This example is to show how to reset the interrupt flags

```
void ClearIntLatch(void)
```

```
{
IIC_ByteWrite(INTRST, 0x03);
IIC_ByteWrite(INTRST, 0x00);
}
```

INT1

- 1: Interrupt assigned by INTRG[1:0] bits in Control 1 Register (\$18) and is detected
- 0: Interrupt assigned by INTRG[1:0] bits in Control 1 Register (\$18) and is not detected

INT2

- 1: Interrupt assigned by INTRG[1:0] bits in Control 1 Register (\$18) and is detected
- 0: Interrupt assigned by INTRG[1:0] bits in Control 1 Register (\$18) and is not detected

DIGITAL INTERFACE

The MMA7455L has both an I²C and SPI digital output available for a communication interface. CS pin is used for selecting the mode of communication. When CS is low, SPI communication is selected. When CS is high, I²C communication is selected.

Note: It is recommended to disable I²C during SPI communication to avoid communication errors between devices using a different SPI communication protocol. To disable I²C, set the I²C DIS bit in I²C Device Address register using SPI.

I²C Slave Interface

I²C is a synchronous serial communication between a master device and one or more slave devices. The master is typically a microcontroller, which provides the serial clock signal and addresses the slave device(s) on the bus. The MMA7455L communicates only in slave operation where the device address is \$1D. Multiple read and write modes are available. The protocol supports slave only operation. It does not support Hs mode, "10-bit addressing", "general call" and: "START byte".

SINGLE BYTE READ

The MMA7455L has an 10-bit ADC that can sample, convert and return sensor data on request. The transmission of an 8-bit command begins on the falling edge of SCL. After the eight clock cycles are used to send the command, note that the data returned is sent with the MSB first once the data is received. [Figure 6](#) shows the timing diagram for the accelerometer 8-bit I²C read operation. The Master (or MCU) transmits a start condition (ST) to the MMA7455L, slave address (\$1D), with the R/W bit set to "0" for a write, and the MMA7455L sends an acknowledgement. Then the Master (or MCU) transmits the 10-bit address of the register to read and the MMA7455L sends an acknowledgement. The Master (or MCU) transmits a repeated start condition (SR) and then addresses the MMA7455L (\$1D) with the R/W bit set to "1" for a read from the previously selected register. The Slave then acknowledges and transmits the data from the requested register. The Master does not acknowledge (NAK) it received the transmitted data, but transmits a stop condition to end the data transfer.

MULTIPLE BYTES READ

The MMA7455L automatically increments the received register address commands after a read command is received. Therefore, after following the steps of a single byte read, multiple bytes of data can be read from sequential registers after each MMA7455L acknowledgment (AK) is received until a NACK is received from the Master followed by a stop condition (SP) signalling an end of transmission. See [Figure 7](#).

SINGLE BYTE WRITE

To start a write command, the Master transmits a start condition (ST) to the MMA7455L, slave address (\$1D) with the R/W bit set to “0” for a write, the MMA7455L sends an acknowledgement. Then the Master (MCU) transmits the 8-bit address of the register to write to, and the MMA7455L sends an acknowledgement. Then the Master (or MCU) transmits the 8-bit data to write to the designated register and the MMA7455L sends an acknowledgement that it has received the data. Since this transmission is complete, the Master transmits a stop condition (SP) to the data transfer. The data sent to the MMA7455L is now stored in the appropriate register. See [Figure 8](#).

Figure 6. Single Byte Read - The Master is reading one address from the MMA7455L

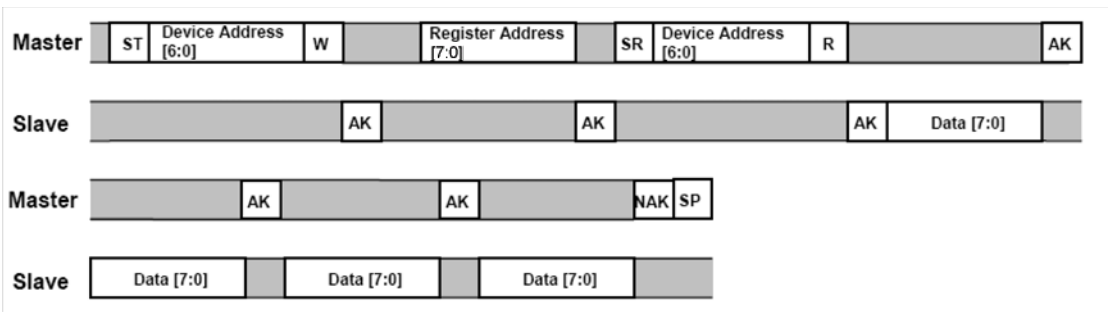

Figure 7. Multiple Bytes Read - The Master is reading multiple sequential registers from the MMA7455L

Figure 8. Single Byte Write - The Master (MCU) is writing to a single register of the MMA7455L

MULTIPLE BYTES WRITE

The MMA7455L automatically increments the received register address commands after a write command is received. Therefore, after following the steps of a single byte write, multiple bytes of data can be written to sequential registers after each MMA7455L acknowledgement (ACK) is received. See [Figure 9](#).

Figure 9. Multiple Byte Writes - The Master (MCU) is writing to multiple sequential registers of the MMA7455L

SPI Slave Interface

The MMA7455L also uses serial peripheral interface communication as a digital communication. The SPI communication is primarily used for synchronous serial communication between a master device and one or more slave devices. See [Figure 15](#) for an example of how to configure one master with one MMA745xL device. The MMA7455L is always operated as a slave device. Typically, the master device would be a microcontroller which would drive the clock (SPC) and chip select (CS) signals.

The SPI interface consists of two control lines and two data lines: CS, SPC, SDI, and SDO. The CS, also known as Chip Select, is the slave device enable which is controlled by the SPI master. CS is driven low at the start of a transmission. CS is then driven high at the end of a transmission. SPC is the Serial Port Clock which is also controlled by the SPI master. SDI and SDO are the Serial Port Data Input and the Serial Port Data Output. The SDI and SDO data lines are driven at the falling edge of the SPC and should be captured at the rising edge of the SPC.

Read and write register commands are completed in 16 clock pulses or in multiples of 8, in the case of a multiple byte read/write.

SPI Read Operation

A SPI read transfer consists of a 1-bit Read/Write signal, a 6-bit address, and 1-bit don't care bit. (1-bit R/W=0 + 6-bits address + 1-bit don't care). The data to read is sent by the SPI interface during the next transfer. See [Figure 10](#) and [Figure 11](#) for the timing diagram for an 8-bit read in 4 wire and 3 wire modes, respectively.

SPI Write Operation

In order to write to one of the 8-bit registers, an 8-bit write command must be sent to the MMA7455L. The write command consists of an MSB (0=read, 1=write) to indicate writing to the MMA7455L register, followed by a 6-bit address and 1 don't care bit.

The command should then be followed the 8-bit data transfer. See [Figure 12](#) for the timing diagram for an 8-bit data write.

Recommended PCB Layout for Interfacing Accelerometer to Microcontroller

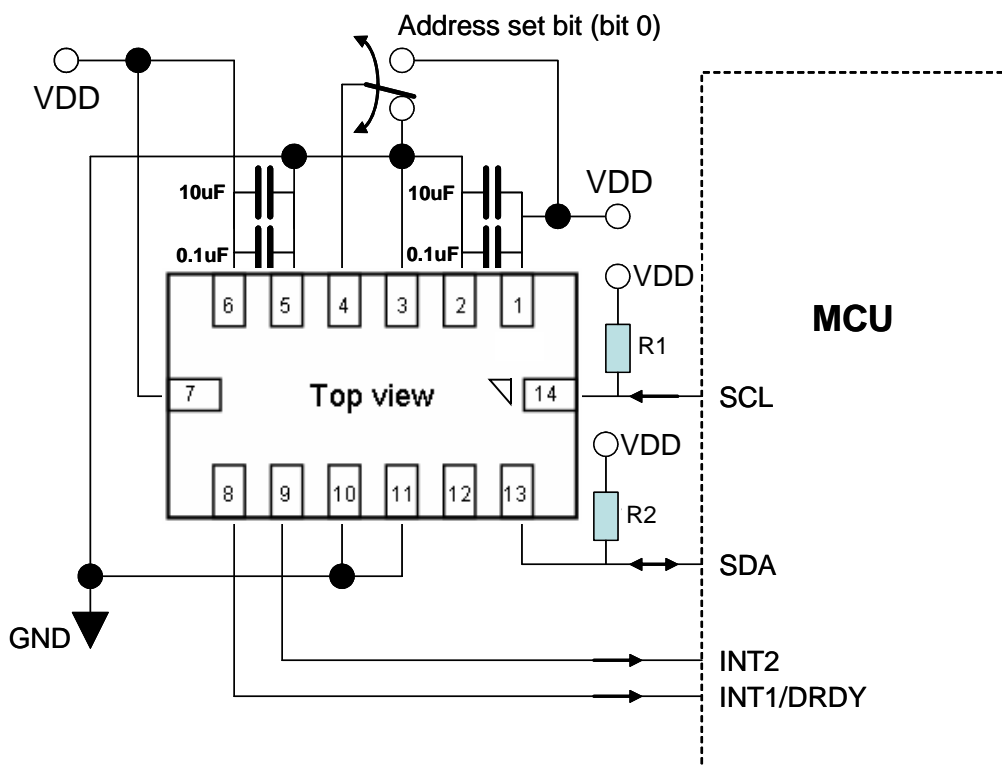

Figure 14. I²C Connection to MCU

Figure 15. SPI Connection to MCU

NOTES:

1. Use a 0.1 μF and a 10 μF capacitor on AV_{DD} to and $\text{DV}_{\text{DD_IO}}$ to decouple the power source.
2. Physical coupling distance of the accelerometer to the microcontroller should be minimal.
3. PCB layout of power and ground should not couple power supply noise.
4. Accelerometer and microcontroller should not be a high current path.
5. Any external power supply switching frequency should be selected such that they do not interfere with the internal accelerometer sampling frequency (sampling frequency). This will prevent aliasing errors.
6. Physical distance of the two GND pins (Pin2 and Pin5) tied together should be at the shortest distance.

Table 9. User Register Summary

Address	Name	Definition	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Bit	ZOFF[10]	ZOFF[9]	ZOFF[8]
Weight*	Polarity	256 LSB	128 LSB

*Bit weight is for 2g 8bit data output. Typical value for reference only. Variation is specified in "Electrical Characteristics" section.

\$16: Mode Control Register (Read/Write)

D7	D6	D5	D4	D3	D2	D1	D0	Bit
--	DRPD	SPI3W	STON	GLVL[1]	GLVL[0]	MODE[1]	MODE[0]	Function
0	0	0	0	0	0	0	0	Default

Table 10. Configuring the g-Select for 8-bit output using Register \$16 with GLVL[1:0] bits.

GLVL [1:0]	g-Range	Sensitivity
00	8g	16 LSB/g
01	2g	64 LSB/g
10	4g	32 LSB/g

GLVL [1:0]

00: 8g is selected for measurement range.

10: 4g is selected for measurement range.

01: 2g is selected for measurement range.

STON

0: Self-test is not enabled

1: Self-test is enabled

SPI3W

0: SPI is 4 wire mode

1: SPI is 3 wire mode

DRPD

0: Data ready status is output to INT1/DRDY PIN

1: Data ready status is not output to INT1/DRDY PIN

\$17: Interrupt Latch Reset (Read/Write)

D7	D6	D5	D4	D3	D2	D1	D0	Bit
--	--	--	--	--	--	CLR_INT2	CLR_INT1	Function
0	0	0	0	0	0	0	0	Default

CLR_INT1

1: Clear "INT1" and LDX/LDY/LDZ or PDX/PDY/PDZ bits in **Detection Source Register (\$0A)** depending on **Control1(\$18) INTREG[1:0]** setting.

0: Do not clear "INT1" LDX/LDY/LDZ or PDX/PDY/PDZ bits in **Detection Source Register (\$0A)**

CLR_INT2

1: Clear "INT2" and LDX/LDY/LDZ or PDX/PDY/PDZ bits in **Detection Source Register (\$0A)** depending on **Control1(\$18) INTREG[1:0]** setting.

0: Do not clear "INT2" and LDX/LDY/LDZ or PDX/PDY/PDZ bits in **Detection Source Register (\$0A)**.

\$18 Control 1 (Read/Write)

D7	D6	D5	D4	D3	D2	D1	D0	Bit
DFBW	THOPT	ZDA	YDA	XDA	INTREG[1]	INTREG[0]	INTPIN	Function
0	0	0	0	0	0	0	0	Default

Table 11. Configuring the Interrupt settings using Register \$18 with INTREG[1:0] bits

INTREG[1:0]	"INT1" Register Bit	"INT2" Register Bit
00	Level detection	Pulse Detection
01	Pulse Detection	Level Detection
10	Single Pulse detection	Single or Double Pulse Detection

01: INT1 Register is detecting Pulse while INT2 is detecting Level.

10: INT1 Register is detecting a Single Pulse and INT2 is detecting Single Pulse (if 2nd Time Window = 0) or if there is a latency time window and second time window > 0 then INT2 will detect the double pulse only.

INTPIN: INT1 pin is routed to INT1 bit in Detection Source Register (\$0A) and INT2 pin is routed to INT2 bit in Detection Source Register (\$0A).

INTPIN: INT2 pin is routed to INT1 bit in Detection Source Register (\$0A) and INT1 pin is routed to INT2 bit in Detection Source Register (\$0A).

Note: When INTREG[1:0] = 10 for the condition to detect single pulse on INT1 and either single or double pulse on INT2, INT1 register bit can no longer be cleared by setting CLR_INT1 bit. It is cleared by setting CLR_INT2 bit. In this case, setting CLR_INT2 clears both INT1 and INT2 register bits and resets the detection operation.

XDA

1: X-axis is disabled for detection.

0: X-axis is enabled for detection.

YDA

1: Y-axis is disabled for detection.

0: Y-axis is enabled for detection.

ZDA

1: Z-axis is disabled for detection.

0: Z-axis is enabled for detection.

THOPT (This bit is valid for level detection only, not valid for pulse detection)

0: Threshold value is absolute only

1: Integer value is available.

DFBW

0: Digital filter band width is 62.5 Hz

1: Digital filter band width is 125 Hz

\$19: Control 2 (Read/Write)

D7	D6	D5	D4	D3	D2	D1	D0	Bit

	0g	\$00
	+1g	\$0F
	+8g	\$7F

MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the surface mount packages must be the correct size to ensure proper solder connection interface between the board and the package.

With the correct footprint, the packages will self-align when subjected to a solder reflow process. It is always recommended to design boards with a solder mask layer to avoid bridging and shorting between solder pads.

SOLDERING AND MOUNTING GUIDELINES FOR THE LGA ACCELEROMETER SENSOR TO A PC BOARD

These guideline are for soldering and mounting the LGA package inertial sensors to printed circuit boards (PCBs). The purpose is to minimize the stress on the package after board mounting. The MMA7455L digital output accelerometer uses the Land Grid Array (LGA) package platform. This section describes suggested methods of soldering these devices to the PC board for consumer applications. Figure 17 shows the recommended PCB land pattern for the package.

Figure 17. Recommended PCB Land Pattern for the 5 x 3 mm LGA Package

OVERVIEW OF SOLDERING CONSIDERATIONS

Information provided here is based on experiments executed on LGA devices. They do not represent exact conditions present at a customer site. Hence, information herein should be used as a guidance only and process and design optimizations are recommended to develop an application specific solution. It should be noted that with the proper PCB footprint and solder stencil designs the package will self-align during the solder reflow process.

The following are the recommended guidelines to follow for mounting LGA sensors for consumer applications.

PCB MOUNTING RECOMMENDATIONS

1. The PCB land should be designed with Non Solder Mask Defined (NSMD) as shown in Figure 20.
2. No additional metal pattern underneath package as shown in Figure 19.
3. PCB land pad is 0.9 mm x 0.6 mm which is the size of the package pad plus 0.1 mm as shown in Figure 20.
4. The solder mask opening is equal to the size of the PCB land pad plus an extra 0.1 mm as shown in Figure 20.
5. The stencil aperture size is equal to the PCB land pad – 0.025mm.

Figure 18. Incorrect PCB Top Metal Pattern Under Package

Figure 19. Correct PCB Top Metal Pattern Under Package

Figure 20. Recommended PCB Land Pad, Solder Mask, and Signal Trace Near Package Design

Figure 21. Stencil Design Guidelines

6. Do not place any components or vias at a distance less than 2 mm from the package land area. This may cause additional package stress if it is too close to the package land area.
7. Signal traces connected to pads should be as symmetric as possible. Put dummy traces on NC pads in order to have same length of exposed trace for all pads. Signal traces with 0.1 mm width and min. 0.5 mm length for all PCB land pads near the package are recommended as shown in [Figure 20](#) and [Figure 21](#). Wider trace can be continued after the 0.5 mm zone.
8. Use a standard pick and place process and equipment. Do not use a hand soldering process.
9. It is recommended to use a cleanable solder paste with an additional cleaning step after SMT mount.
10. Do not use a screw down or stacking to fix the PCB into an enclosure because this could bend the PCB putting stress on the package.
11. The PCB should be rated for the multiple lead-free reflow condition with max 260°C temperature.

Please cross reference with the device data sheet for mounting guidelines specific to the exact device used.

Freescale LGA sensors are compliant with Restrictions on Hazardous Substances (RoHS), having halide free molding compound (green) and lead-free terminations. These terminations are compatible with tin-lead (Sn-Pb) as well as tin-silver-copper (Sn-Ag-Cu) solder paste soldering processes. Reflow profiles applicable to those processes can be used successfully for soldering the devices.
